The DNA pattern of 14 rhabdomyosarcomas was studied by the gel electrophoresis of DNA isolated from the neoplastic tissue. Unusual DNA ladders of various sizes were found in all the tumors analysed; moreover, a heterogeneous population of DNA fragments was demonstrated in two cases. Similar results were obtained when purified tumor DNA was separated by the agarose gel electrophoresis. These findings, which appear to confirm the loss of genetic information and the presence of an abnormal DNA pattern in these tumors, are correlated with some pathologic findings and discussed./* * Copyright 2012-2019 the original author or authors. * * Licensed under the Apache License, Version 2.0 (the "License"); * you may not use this file except in compliance with the License. * You may obtain a copy of the License at * * * * Unless required by applicable law or agreed to in writing, software * distributed under the License is distributed on an "AS IS" BASIS, * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. * See the License for the specific language governing permissions and * limitations under the License. */ package org.springframework.boot.configurationmetadata; import java.util.List; import org.junit.jupiter.api.Test; import org.springframework.beans 5b5f913d15
